# Dirichlet Series From Primes To Riemann

Tariq Rashid

June 23, 2021

1/16

#### Dirichlet Series

• Dirichlet series have the general form

$$\sum a_n/n^s$$

- ... in contrast to familiar power series  $\sum a_n z^n$ .
- The Riemann Zeta series is an example of a Dirichlet series.

$$\zeta(s) = \sum \frac{1}{n^s} = \frac{1}{1^s} + \frac{1}{2^s} + \frac{1}{3^s} + \frac{1}{4^s} + \dots$$

2 / 16

## Absolute Convergence

- A series **converges absolutely** even when all its terms are replaced by their magnitudes.
- Not all series that converge do so absolutely.

$$1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \ldots \to \infty$$

$$1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \frac{1}{5} + \ldots \rightarrow \ln(2)$$

## Abscissa of Absolute Convergence

- Assume a Dirichlet series converges absolutely at  $s_1 = \sigma_1 + it_1$ . Consider another  $s_2 = \sigma_2 + it_2$  where  $\sigma_2 > \sigma_1$ .
- Compare the magnitudes of the terms in this series at  $s_1$  and  $s_2$ .

$$\sum \left| \frac{a_n}{n^{s_1}} \right| = \sum \frac{|a_n|}{n^{\sigma_1}} \ge \sum \frac{|a_n|}{n^{\sigma_2}} = \sum \left| \frac{a_n}{n^{s_2}} \right|$$

- Remember  $|n^{\sigma+it}| = |n^{\sigma}e^{it \ln n}| = n^{\sigma}$ .
- So if series converges at  $s_1$ , it must also converge at  $s_2$ . More generally, the series converges at any  $s = \sigma + it$  where  $\sigma \geq \sigma_1$ .

4 / 16

#### Abscissa of Absolute Convergence

- If our series doesn't converge everywhere, divergence must be at some  $\sigma < \sigma_1$ . There must be a minimum  $\sigma_a$ , called the abscissa of absolute convergence, such that the series converges at  $\sigma > \sigma_a$ .
- Notice  $\sigma_a$  depends only on the real part of s. Example:
  - $\sum 1/n^{\sigma}$  converges for real  $\sigma>1$ , and it diverges at  $\sigma=1$
  - $\implies \sigma_a = 1$ , so series converges for all  $s = \sigma + it$  where  $\sigma > 1$ .
- Convergence domain for a Dirichlet series is a half-plane, whereas the region for the more familiar power series  $\sum a_n z^n$  is a circle.

5 / 16

- With absolute convegence we don't need to consider complex terms which contibute a negative amount to the overall magnitude of the series.
  - Example,  $e^{i\pi}=-1$  can partially cancel the effect  $2e^{i2\pi}=2$ .
  - This cancelling means some series do converge, even if not absolutely.
- Strategy:
  - show that if a series is **bounded** at  $s_0 = \sigma_0 + it_0$  then it is also **bounded** at  $s = \sigma + it$ , where  $\sigma > \sigma_0$
  - then push further to show it actually converges at that s.

6 / 16

• Start with a Dirichlet series  $\sum a_n/n^s$  that we know has bounded partial sums at a point  $s_0 = \sigma_0 + it_0$  for all  $x \ge 1$ .

$$\left|\sum_{n\leq x}\frac{a_n}{n^{s_0}}\right|\leq M$$

 Being bounded is not as strong a requirement as convergence, the partial sums could oscillate for example.

 Abel's partial summation formula relates a discrete sum to a continuous integral.

$$\sum_{x_1 < n \le x_2} b_n f(n) = B(x_2) f(x_2) - B(x_1) f(x_1) - \int_{x_1}^{x_2} B(t) f'(t) dt$$

- Define  $f(x) = x^{s_0-s}$  and  $b_n = a_n/n^{s_0}$ .
- B(x) is defined as  $\sum_{n \le x} b_n$ , and so  $|B(x)| \le M$  for all x.

$$\sum_{x_1 < n \le x_2} \frac{a_n}{n^s} = \sum_{x_1 < n \le x_2} b_n f(n)$$

$$=\frac{B(x_2)}{x_2^{s-s_0}}-\frac{B(x_1)}{x_1^{s-s_0}}+(s-s_0)\int_{x_1}^{x_2}\frac{B(t)}{t^{s-s_0+1}}dt$$

• Using triangle inequality and  $|B(x)| \leq M$ .

$$\left| \sum_{x_1 < n \le x_2} \frac{a_n}{n^s} \right| \le \left| \frac{B(x_2)}{x_2^{s-s_0}} \right| + \left| \frac{B(x_1)}{x_1^{s-s_0}} \right| + \left| (s-s_0) \int_{x_1}^{x_2} \frac{B(t)}{t^{s-s_0+1}} dt \right|$$

$$\leq Mx_2^{\sigma_0-\sigma} + Mx_1^{\sigma_0-\sigma} + |s-s_0| M \int_{x_1}^{x_2} t^{\sigma_0-\sigma-1} dt$$

9/16

• Using  $Mx_2^{\sigma_0-\sigma}+Mx_1^{\sigma_0-\sigma}<2Mx_1^{\sigma_0-\sigma}$  for  $\sigma>\sigma_0$ .

$$\left| \sum_{x_1 < n \le x_2} \frac{a_n}{n^s} \right| \le 2Mx_1^{\sigma_0 - \sigma} + |s - s_0| M\left(\frac{x_2^{\sigma_0 - \sigma} - x_1^{\sigma_0 - \sigma}}{\sigma_0 - \sigma}\right)$$

$$\leq 2Mx_1^{\sigma_0-\sigma}\left(1+\frac{|s-s_0|}{\sigma-\sigma_0}\right)$$

• Last step uses  $\left|x_2^{\sigma_\mathbf{0}-\sigma}-x_1^{\sigma_\mathbf{0}-\sigma}\right|=x_1^{\sigma_\mathbf{0}-\sigma}-x_2^{\sigma_\mathbf{0}-\sigma}< x_1^{\sigma_\mathbf{0}-\sigma}< 2x_1^{\sigma_\mathbf{0}-\sigma}$ 

- 4 ロ > 4 個 > 4 差 > 4 差 > - 差 - 夕 Q @

10 / 16

- The key point is that  $\sum_{x_1 < n \le x_2} a_n / n^s$  is bounded if  $\sum_{n \le x} a_n / n^{s_0}$  is bounded, where  $\sigma > \sigma_0$ .
- Let's see if we can push this result about boundedness to convergence.

Tariq Rashid Dirichlet Series June 23, 2021 11/16

$$\left| \sum_{x_1 < n \le x_2} \frac{a_n}{n^s} \right| \le 2M x_1^{\sigma_0 - \sigma} \left( 1 + \frac{|s - s_0|}{\sigma - \sigma_0} \right) = K x_1^{\sigma_0 - \sigma}$$

- Here K doesn't depend on x<sub>1</sub>.
- If we let  $x_1 \to \infty$  then  $Kx_1^{\sigma_0 \sigma} \to 0$ , which means the infinite sum  $\sum a_n/n^s$  converges.

#### Results So Far

- If  $\sum_{n \le x} a_n/n^{s_0}$  is bounded, the infinite sum  $\sum a_n/n^s$  converges for  $\sigma > \sigma_0$ .
- With the special case of  $s_0 = 0$ , if  $\sum_{n \le x} a_n$  is bounded, the infinite sum  $\sum a_n/n^s$  converges for  $\sigma > 0$ .
  - We can sometimes say whether a series converges for  $\sigma > 0$  just by looking at the coefficients  $a_n$ .

Tarig Rashid Dirichlet Series June 23, 2021 13 / 16

- There is an abscissa of convergence  $\sigma_c$  where a Dirichlet series converges for  $\sigma > \sigma_c$ , and diverges for  $\sigma < \sigma_c$ .
  - If a series converges (bounded) at  $s_0$  then it converges at  $\sigma>\sigma_0$
  - If series doesn't converge everywhere, the s where it diverges has  $\sigma < \sigma_0$

Tariq Rashid Dirichlet Series June 23, 2021 14 / 16

#### Difference Between $\sigma_c$ And $\sigma_a$

- Not all convergent series are absolutely convergent, so  $\sigma_a \geq \sigma_c$ .
- If a series converges at  $s_0$ , the magnitude of terms is bounded. We can call this bound C.

$$\sum \left| \frac{a_n}{n^s} \right| = \sum \left| \frac{a_n}{n^{s_0}} \cdot \frac{1}{n^{s-s_0}} \right| \le C \sum \frac{1}{n^{\sigma-\sigma_0}}$$

•  $\sum n^{\sigma_0-\sigma}$  only converges for  $\sigma_0-\sigma>1$ , so we can say if  $\sigma$  is larger than  $\sigma_c$  by at least 1, the series converges absolutely.

$$\boxed{0 \leq \sigma_{a} - \sigma_{c} \leq 1}$$

#### Example: Alternating Zeta Function

 Let's apply our results to the alternating zeta function, also called the eta function.

$$\eta(s) = \sum \frac{(-1)^{n+1}}{n^s} = \frac{1}{1^s} - \frac{1}{2^s} + \frac{1}{3^s} - \frac{1}{4^s} + \dots$$

- At  $s_0=0$  the partial sum  $\sum_{n\leq x} (-1)^{n+1}$  oscillates but is always bounded  $\leq 1$
- $\implies \sum (-1)^{n+1}/n^s$  converges for  $\sigma > 0$ .
